SE – 203: Software Requirement Engineering

CONTENTS

Lab Session No.	Object
01-02	To understand the concept of Feasibility Study.
03-04	Project Planning and Management.
05-06	Software Requirement Specification (SRS).
07-08	Introduction to UML and Use Case Diagram.
09-10	To understand Class and Interaction Diagram.
11-12	To understand State Diagram.
13-14-15	To understand System Modeling.

Note: The following software is used: MS Visio

Lab # 1 and 2

Object:

To understand the concept of Feasibility Study.

Theory:

The Feasibility Study is a combination of a market study and an economic analysis that provides an investor with knowledge of both the environment where a project exists and the expected return on investment to be derived from it.

Feasibility Study may also be defined as:

- A preliminary study undertaken before the real work of a project starts to ascertain the likelihood of the projects success.
- A small-scale investigation of a problem to ascertain whether a proposed research approach is likely to provide useful data.
- An analysis of the practicability of a proposal.
- A study that usually recommends selection of a cost-effective alternative.
- A study that decides whether or not the proposed system is worthwhile.

Feasibility Study is a study undertaken:

- To assess in broad terms of technology, cost and time the feasibility of meeting a Staff Target.
- To identify alternative solutions, their relative advantages and disadvantages, and key problem areas for further study.
- To provide detailed costed proposals for project definition studies and information in the detail necessary to draft a Staff Requirement.
- To check:
 - If the system contributes to organizational objectives.
 - If the system can be engineered using current technology and within budget.
 - If the system can be integrated with other systems that are used.

The feasibility study results in a written document called the Feasibility Report. The following outline for the Feasibility Report is close to the one suggested by Pressman.

- Cover Sheet.
- Executive Summary - Management Summary and Recommendations.
- A summary of important findings and recommendations for further system development. Should be maximum of one page and self-contained, i.e., no references to tables or figures.
- Introduction.
- Background.
- Alternatives.
- System Description.
- Cost-Benefit Analysis.
- Evaluation of Technical Risk.
- A presentation of technical feasibility.
- Legal Ramifications.

Exercise:

1. Make a feasibility report of the chosen project.

Lab # 3 and 4

Object:

Project Planning and Management.

Theory:

Project management is the process of planning and controlling the development of a system within a specified timeframe at a minimum cost with the right functionality.

Project Work Plan

Prepare a list of all tasks in the work breakdown structure, plus:

- Duration of task.
- Current task status.
- Task dependencies.
- Key milestone dates.

Tracking Progress

- Gantt Chart:
 - Project control technique for scheduling, budgeting and resource planning.
 - Useful to monitor project status at any point in time.
 - Can be used for resource allocation and staff planning.
- PERT (Program Evaluation and Review Technique) Chart:
 - Flowchart format.
 - Illustrate task dependencies and critical path.

Software Cost Estimation.

- Principal components of project costs derive from:
 - hardware and software including maintenance.
 - travel and training.
 - effort (cost of paying software engineers).
- Initial Cost Estimation should be based on firm, complete requirements.
- Continual Cost Estimation is required to ensure that spending is in line with budget.
- Software Cost Estimation should use multiple techniques to predict costs:
 - historical cost information relating metrics and costs.
 - analogies to similar systems.

Project Duration, Staffing and Team Organization.

- Project managers have also to estimate:
 - how long a software product will take to develop.
 - when how many people will be needed to work on the project.
- More people working on a project also requires more communication overhead.
- Large software systems require a coordinated team of software engineers for effective development.
- Team organization involves devising roles for individuals and assigning responsibilities.
- Organizational structure attempts to facilitate cooperation.
- For long-term projects, job satisfaction is extremely important for reduced turnover.
- Need mix of senior and junior engineers to facilitate both accomplishing the task and training.

- Adding people to a project introduces further delays.
- Hierarchical organizations minimize and discourage communication, while democratic organizations encourage it.
- Appropriate organization depends on project length and complexity:
 - small teams lead to cohesive design, less overhead, more unity, higher morale.
 - but some tasks too complex.
 - optimal size between 3 and 8.
- Appropriate design leads to appropriate assignment of tasks and appropriate team organization.

Risk Management

A *risk* is a probability that some adverse circumstance will occur.

Risk management is concerned with identifying risks and drawing up plans to minimize their effect on a project.

- **Project** risks which affect schedule or resources.
- **Product** risks which affect the quality or performance of the software being developed.
- **Business** risks which affect the organization developing the software.

Risk Management Process

- Risk identification: identify project, product and business risks.
- Risk analysis: assess the likelihood and consequences of these risks.
- Risk planning: draw up plans to avoid / minimize the effects of the risk.
- Risk monitoring: monitor the risks throughout the project.

CASE Tools

Microsoft Project is the clear market leader among desktop project management applications.

.

Exercise:

1. Use MS Project to create a series of tasks leading to completion of your project. For your project, you need to:

- Set start or ending dates.
- Develop a list of tasks that need to be completed.
- Establish any sub tasks and create links.
- Create any links between major tasks.
- Assign a specific amount time for each task.
- Assign resources for each task.
- Create task information for each item you put into the list.

Lab # 5 and 6

Object:

Software Requirement Specification (SRS).

Theory:

A requirement is a statement of a behavior or attribute that a system must possess for the system to be acceptable to a stakeholder.

Software Requirement Specification (SRS) is a document that describes the requirements of a computer system from the user's point of view. An SRS document specifies:

- The required behavior of a system in terms of: input data, required processing, output data, operational scenarios and interfaces.
- The attributes of a system including: performance, security, maintainability, reliability, availability, safety requirements and design constraints.

Requirements management is a systematic approach to eliciting, organizing and documenting the requirements of a system. It is a process that establishes and maintains agreement between the customer and the project team on the changing requirements of a system.

Requirements management is important because, by organizing and tracking the requirements and managing the requirement changes, you improve the chances of completing the project on time and under budget. Poor change management is a key cause of project failure.

Requirements Engineering Process

Requirements engineering process consists of four phases:

- **Requirements elicitation:** getting the customers to state exactly what the requirements are.
- **Requirements analysis:** making qualitative judgments and checking for consistency and feasibility of requirements.
- **Requirements validation:** demonstrating that the requirements define the system that the customer really wants.
- **Requirements management:** the process of managing changing requirements. during the requirements engineering process and system development, and identifying missing and extra requirements.

Writing Requirements

Requirements always need to be correct, unambiguous, complete, consistent, and testable.

Recommendations When Writing Requirements

- Never assume: others do not know what you have in mind.
- Use meaningful words; avoid words like: process, manage, perform, handle, and support.
- State requirements not features:
 - Feature: general, tested only for existence.

- Requirement: specific, testable, measurable.
- Avoid:
 - Conjunctions: ask yourself whether the requirement should it be split into two requirements.
 - Conditionals: if, else, but, except, although.
 - Possibilities: may, might, probably, usually.

Writing Specifications

Specification is a description of operations and attributes of a system. It can be a document, set of documents, a database of design information, a prototype, diagrams or any combination of these things.

Specifications are different from requirements: specifications are sufficiently complete — not only what stakeholders say they want; usually, they have no conflicts; they describe the system as it will be built and resolve any conflicting requirements.

Creating specifications is important. However, you may not create specifications if:

- You are using a very incremental development process (small changes).
- You are building research or proof of concept projects.
- You rebuilding very small projects.
- It is not cheaper or faster than building the product.

Software Requirement Specification (SRS)

Remember that there is no “Perfect SRS”. However, SRS should be:

- **Correct:** each requirement represents something required by the target system.
- **Unambiguous:** every requirement in SRS has only one interpretation.
- **Complete:** everything the target system should do is included in SRS (no sections are marked TBD-to be determined).
- **Verifiable:** there exists some finite process with which a person/machine can check that the actual as-built software product meets the requirements.
- Consistent in behavior and terms.
- Understandable by customers.
- **Modifiable:** changes can be made easily, completely and consistently.
- **Design independent:** doesn't imply specific software architecture or algorithm.
- **Concise:** shorter is better.
- **Organized:** requirements in SRS are easy to locate; related requirements are together.
- **Traceable:** each requirement is able to be referenced for later use (by the using paragraph numbers, one requirement in each paragraph, or by using convention for indication requirements).

Exercise:

1. Prepare and submit an SRS for your project.

Lab # 7 and 8

Object:

Introduction to UML and Use Case Diagram.

Theory:

The Unified Modeling Language (UML) is a standard language for specifying, visualizing, constructing, and documenting the artifacts of software systems, as well as for business modeling and other non-software systems.

The UML is a very important part of developing object oriented software and the software development process. The UML uses mostly graphical notations to express the design of software projects. Using the UML helps project teams communicate, explore potential designs, and validate the architectural design of the software.

Types of UML Diagrams

Each UML diagram is designed to let developers and customers view a software system from a different perspective and in varying degrees of abstraction.

UML diagrams commonly created in visual modeling tools include:

- **Use Case Diagram** displays the relationship among actors and use cases.
- **Class Diagram** models class structure and contents using design elements such as classes, packages and objects. It also displays relationships such as containment, inheritance, associations and others.
- **Interaction Diagrams**
 - **Sequence Diagram** displays the time sequence of the objects participating in the interaction. This consists of the vertical dimension (time) and horizontal dimension (different objects).
 - **Collaboration Diagram** displays an interaction organized around the objects and their links to one another. Numbers are used to show the sequence of messages.
- **State Diagram** displays the sequences of states that an object of an interaction goes through during its life in response to received stimuli, together with its responses and actions.
- **Activity Diagram** displays a special state diagram where most of the states are action states and most of the transitions are triggered by completion of the actions in the source states. This diagram focuses on flows driven by internal processing.
- **Physical Diagrams.**
 - **Component Diagram** displays the high level packaged structure of the code itself. Dependencies among components are shown, including source code components, binary code components, and executable components. Some components exist at compile time, at link time, at run times well as at more than one time.
 - **Deployment Diagram** displays the configuration of run-time processing elements and the software components, processes, and objects that live on them. Software component instances represent run-time manifestations of code units.

Use Case Diagrams.

A use case is a set of scenarios that describing an interaction between a user and a system. A use case diagram displays the relationship among actors and use cases. The two main components of a use case diagram are use cases and actors.

An actor is represents a user or another system that will interact with the system you are modeling. A use case is an external view of the system that represents some action the user might perform in order to complete a task.

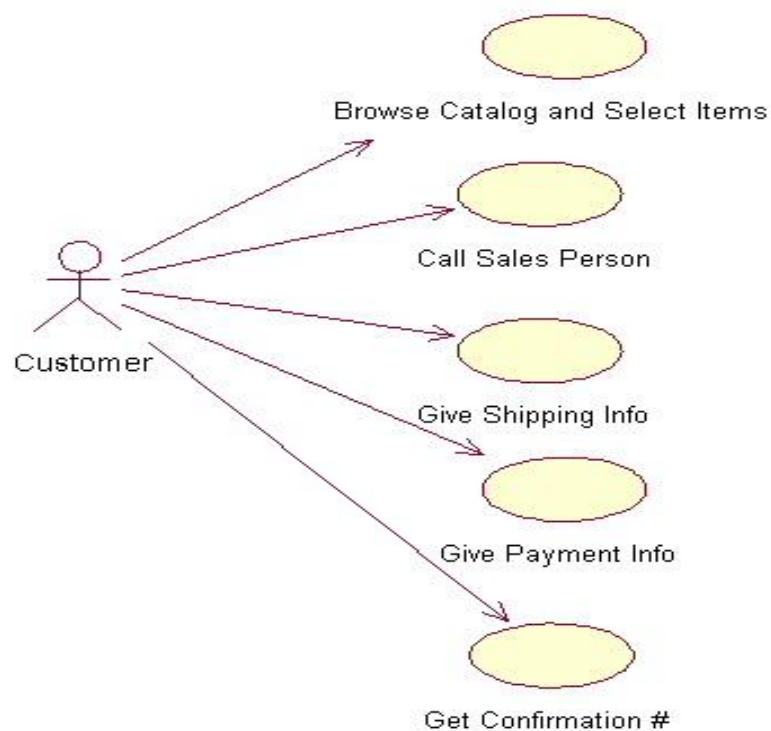

When to Use: Use Cases Diagrams.

Use cases are used in almost every project. They are helpful in exposing requirements and planning the project. During the initial stage of a project most use cases should be defined, but as the project continues more might become visible.

How to Draw: Use Cases Diagrams.

For example a user placing an order with a sales company might follow these steps.

1. Browse catalog and select items.
2. Call sales representative.
3. Supply shipping information.
4. Supply payment information.
5. Receive conformation number from salesperson.

Exercise:

1. Draw USE CASE DIAGRAM of your project.

Lab # 9 and 10

Object:

To understand Class and Interaction Diagram.

Theory:

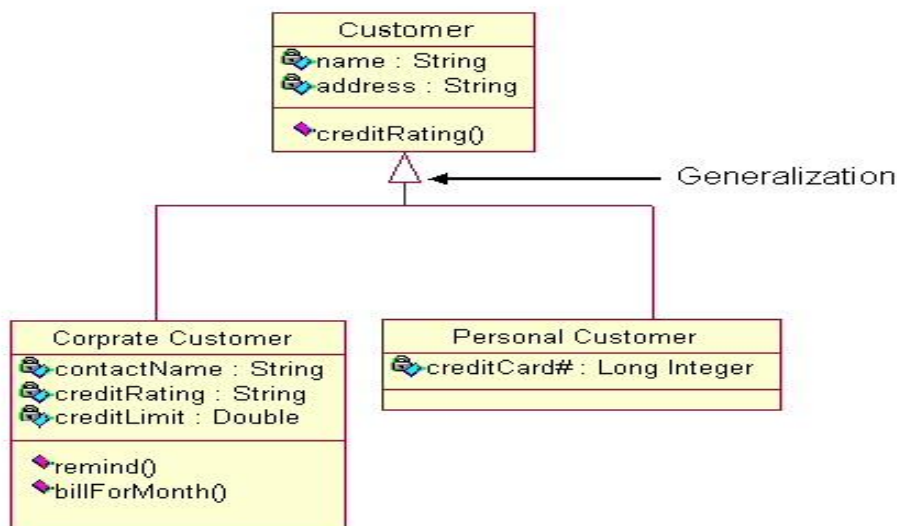

Class diagrams are widely used to describe the types of objects in a system and their relationships. Class diagrams model class structure and contents using design elements such as classes, packages and objects. Classes are composed of three things: a name, attributes, and operations. Below is an example of a class

Class diagrams also display relationships such as containment, inheritance, associations and others. The association shows the relationship between instances of classes.

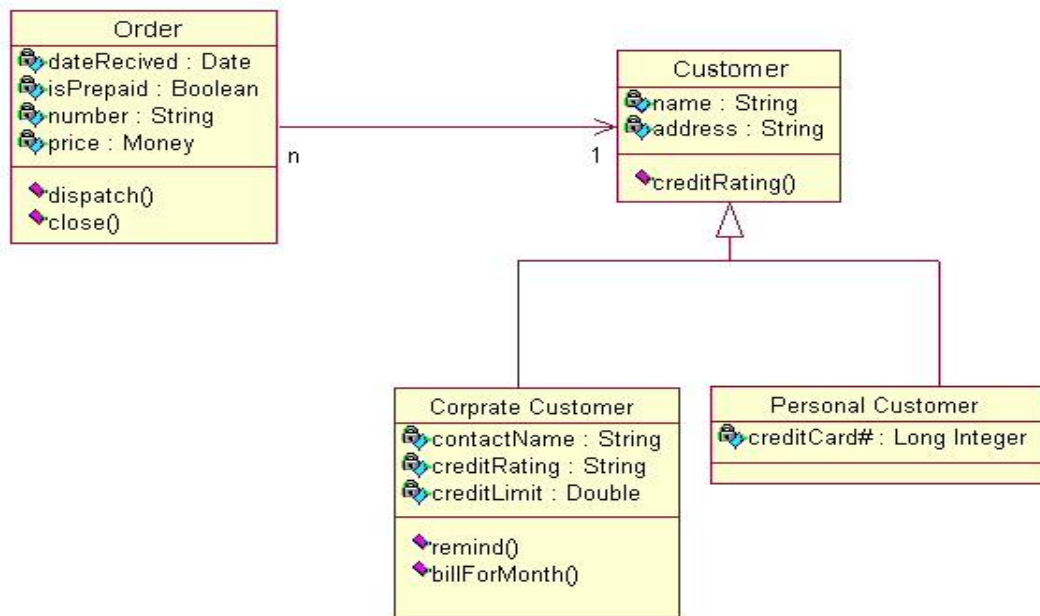

A generalization is used when two classes are similar, but have some differences.

When to Use: Class Diagrams.

Class diagrams are used in nearly all Object Oriented software designs. Use them to describe the Classes of the system and their relationships to each other.

Interaction Diagrams.

Interaction diagrams model the behavior of use cases by describing the way groups of objects interact to complete the task. The two kinds of interaction diagrams are **sequence** and **collaboration** diagrams. This example is only meant as an introduction to the UML and interaction diagrams.

When to Use: Interaction Diagrams.

Interaction diagrams are used when you want to model the behavior of several objects in a use case. They demonstrate how the objects collaborate for the behavior. Interaction diagrams do not give a in depth representation of the behavior.

How to Draw: Interaction Diagrams.

Sequence diagrams, collaboration diagrams, or both diagrams can be used to demonstrate the interaction of objects in a use case. Sequence diagrams generally show the sequence of events that occur. Collaboration diagrams demonstrate how objects are statically connected. Both diagrams are relatively simple to draw and contain similar elements.

Sequence diagrams.

Sequence diagrams demonstrate the behavior of objects in a use case by describing the objects and the messages they pass. The diagrams are read left to right and descending. The example below shows an object of class 1 start the behavior by sending a message to an object of class 2. Messages pass between the different objects until the object of class 1 receives the final message.

Collaboration diagrams.

Collaboration diagrams are also relatively easy to draw. They show the relationship between objects and the order of messages passed between them. The objects are listed as icons and arrows indicate the messages being passed between them. The numbers next to the messages are called sequence numbers. As the name suggests, they show the sequence of the messages as they are passed between the objects. There are many acceptable sequence numbering schemes in UML. A simple 1, 2, 3... format can be used, or for more detailed and complex diagrams a 1, 1.1 ,1.2, 1.2.1... scheme can be used.

Exercise:

1. Draw Class and Interaction Diagram of your project.

Lab # 11 and 12

Object:

To understand State Diagram.

Theory:

State diagrams are used to describe the behavior of a system. State diagrams describe all of the possible states of an object as events occur. Each diagram usually represents objects of a single class and track the different states of its objects through the system.

When to Use: State Diagrams.

Use state diagrams to demonstrate the behavior of an object through many use cases of the system.

Only use state diagrams for classes where it is necessary to understand the behavior of the object through the entire system.

Not all classes will require a state diagram and state diagrams are not useful for describing the collaboration of all objects in a use case.

State diagrams are other combined with other diagrams such as interaction diagrams and activity diagrams.

How to Draw: State Diagrams.

State diagrams have very few elements. The basic elements are rounded boxes representing the state of the object and arrows indicating the transition to the next state. The activity section of the state symbol depicts what activities the object will be doing while it is in that state.

All state diagrams begin with an initial state of the object. This is the state of the object when it is created. After the initial state the object begins changing states. Conditions based on the activities can determine what the next state the object transitions to.

Exercise:

1. Draw State Diagram of your project.

Lab # 13, 14 and 15

Object:

To understand System Modeling.

Theory:

Modeling consists of building an abstraction of reality. These abstractions are simplifications because they ignore irrelevant details and they only represent the relevant details (what is relevant or irrelevant depends on the purpose of the model).

Why Model Software?

Software is getting larger, not smaller; for example, Windows XP has more than 40 million lines of code. A single programmer cannot manage this amount of code in its entirety. Code is often not directly understandable by developers who did not participate in the development; thus, we need simpler representations for complex systems (modeling is a mean for dealing with complexity).

A wide variety of models have been in use within various engineering disciplines for a long time. In software engineering a number of modeling methods are also available.

Analysis Model Objectives.

- To describe what the customer requires.
- To establish a basis for the creation of a software design.
- To define a set of requirements that can be validated once the software is built.

The Elements of the Analysis Model.

The generic analysis model consists of:

- An entity-relationship diagram (data model).
- A data flow diagram (functional model).
- A state transition diagram (behavioral model).

Entity Relationship Diagram.

An entity relationship diagram (ERD) is one means of representing the objects and their relationships in the data model for a software product.

Entity Relationship diagram notation.

Entity

Relationship

To create an ERD you need to:

- Define “objects” by underlining all nouns in the written statement of scope: producers/consumers of data, places where data are stored, and “composite” data items.
- Define “operations” by double underlining all active verbs: processes relevant to the application and data transformations.
- Consider other “services” that will be required by the objects.
- Then you need to define the relationship which indicates “connectedness”: a "fact" that must be "remembered" by the system and cannot be or is not computed or derived mechanically.

Data Flow Diagram.

A data flow data diagram is one means of representing the functional model of a software product. DFDs do not represent program logic like flowcharts do.

Data flow diagram notation.

To create a DFD you need to:

- Review ERD to isolate data objects and grammatical parse to determine operations.
- Determine external entities (producers and consumers of data).
- Create a level 0 DFD “Context Diagram” (one single process).
- Balance the flow to maintain data flow continuity.
- Develop a level 1 DFD; use a 1:5 (approx.) expansion ratio.

Data Flow Diagram Guidelines.

- All icons must be labeled with meaningful names.
- Always show external entities at level 0.
- Always label data flow arrows.
- Do not represent procedural logic.
- Each bubble is refined until it does just one thing.

Exercise:

1. Prepare and ERD and DFD of your project.
