4		Banker's Algorithm for Dead Lock Avoidance and Dead Lock Prevention	
5	A	FIFO(First In First Out) Page Replacement	
	B	LRU(Least Recent Used) Page Replacement	
	C	Optimal Page Replacement(LFU)	
6		Paging Memory Allocation Technique	
7		Segmentation Memory Allocation Technique	

Note: The following software is used: Turbo C (Free Version)

Ex. No:1(a)

## ROUND ROBIN SCHEDULING

Aim: Write a C program to implement the various process scheduling mechanisms such as Round Robin Scheduling.

### Algorithm for RR

Step 1: Start the process

Step 2: Accept the number of processes in the ready Queue and time quantum (or) time slice

Step 3: For each process in the ready Q, assign the process id and accept the CPU burst time

Step 4: Calculate the no. of time slices for each process where

$\text{No. of time slice for process}(n) = \text{burst time process}(n) / \text{time slice}$

Step 5: If the burst time is less than the time slice then the no. of time slices =1.

Step 6: Consider the ready queue is a circular Q, calculate

(a) Waiting time for process(n) = waiting time of process(n-1)+ burst time of process(n-1) + the time difference in getting the CPU from process(n-1)

(b) Turn around time for process(n) = waiting time of process(n) + burst time of process(n)+ the time difference in getting CPU from process(n).

Step 7: Calculate

(a) Average waiting time = Total waiting Time / Number of process

(b) Average Turnaround time = Total Turnaround Time / Number of process

Step 8: Stop the process

/\* ROUND ROBIN SCHEDULING ALGORITHM \*/

```

#include<stdio.h>
#include<conio.h>

void main()
{
    int ts,pid[10],need[10],wt[10],tat[10],i,j,n,n1;
    int bt[10],flag[10],ttat=0,twt=0;
    float awt,atat;
    clrscr();

    printf("\t\t ROUND ROBIN SCHEDULING \n");
    printf("Enter the number of Processors \n");
    scanf("%d",&n);

    n1=n;
    printf("\n Enter the Timeslice \n");
    scanf("%d",&ts);
    for(i=1;i<=n;i++)
    {
        printf("\n Enter the process ID %d",i);
        scanf("%d",&pid[i]);
        printf("\n Enter the Burst Time for the process");
        scanf("%d",&bt[i]);
        need[i]=bt[i];
    }
    for(i=1;i<=n;i++)
    {
        flag[i]=1;
        wt[i]=0;
    }
    while(n!=0)
    {
        for(i=1;i<=n;i++)
        {

}

printf("\n The average Waiting Time=4.2f",awt);
printf("\n The average Turn around Time=4.2f",atat);
getch();
}

```

### OUTPUT:

ROUND ROBIN SCHEDULING

Enter the number of Processors

4

Enter the Timeslice

5

Enter the process ID 1 5

Enter the Burst Time for the process 10

Enter the process ID 2 6

Enter the Burst Time for the process 15

Enter the process ID 3 7

Enter the Burst Time for the process 20

Enter the process ID 4 8

Enter the Burst Time for the process 25

### ROUND ROBIN SCHEDULING ALGORITHM

Process	Process ID	BurstTime	Waiting Time	TurnaroundTime
1	5	10	15	25
2	6	15	25	40
3	7	20	25	45
4	8	25	20	45

The average Waiting Time=4.2f

The average Turn around Time=4.2f

### Ex. No: 1(b) SJF SCHEDULING

Aim: Write a C program to implement the various process scheduling mechanisms such as SJF Scheduling .

#### Algorithm for SJF

Step 1: Start the process

Step 2: Accept the number of processes in the ready Queue

Step 3: For each process in the ready Q, assign the process id and accept the CPU burst time

Step 4: Start the Ready Q according the shortest Burst time by sorting according to lowest to

highest burst time.

Step 5: Set the waiting time of the first process as '0' and its turnaround time as its burst time.

Step 6: For each process in the ready queue, calculate

(a) Waiting time for process(n)= waiting time of process (n-1) + Burst time of process(n-1)

(b) Turn around time for Process(n)= waiting time of Process(n)+ Burst time for process(n)

Step 6: Calculate

(c) Average waiting time = Total waiting Time / Number of process

(d) Average Turnaround time = Total Turnaround Time / Number of process

Step 7: Stop the process

/\* SJF SCHEDULING ALGORITHM \*/

```
#include<stdio.h>
void main()
{
    int i,j,k,n,sum,wt[10],tt[10],tw,tat;
    int t[10],p[10];
    float awt,atat;
    clrscr();

    printf("Enter number of process\n");
    scanf("%d",&n);

    for(i=0;i<n;i++)
    {
```

```

    printf("\n Enter the Burst Time of Process %d",i);
    scanf("\n %d",&t[i]);
}

for(i=0;i<n;i++)
    p[i]=i;
for(i=0;i<n;i++)

    printf("\n AVERAGE TURN AROUND TIME %4.2f",atat);
    getch();
}
}

```

### OUTPUT:

Enter number of process  
3

Enter the Burst Time of Process 04

Enter the Burst Time of Process 13

Enter the Burst Time of Process 25

### SHORTEST JOB FIRST SCHEDULING ALGORITHM

PROCESS ID	BURST TIME	WAITING TIME	TURNAROUND TIME
1	3	0	3
0	4	3	7
2	5	7	12

AVERAGE WAITING TIME 3.33

AVERAGE TURN AROUND TIME 7.33

Ex. No: 1(c)

## FCFS SCHEDULING

Aim: Write a C program to implement the various process scheduling mechanisms such

Algorithm for FCFS scheduling:

Step 1: Start the process

Step 2: Accept the number of processes in the ready Queue

Step 3: For each process in the ready Q, assign the process id and accept the CPU burst time

Step 4: Set the waiting of the first process as '0' and its burst time as its turn around time

Step 5: for each process in the Ready Q calculate

(c) Waiting time for process(n)= waiting time of process (n-1) + Burst time of process(n-1)

(d) Turn around time for Process(n)= waiting time of Process(n)+ Burst time for process(n)

Step 6: Calculate

(e) Average waiting time = Total waiting Time / Number of process

(f) Average Turnaround time = Total Turnaround Time / Number of process

Step 7: Stop the process

## ``` /* FCFS SCHEDULING ALGORITHM */ ```

```
#include<stdio.h>
void main()
{
    int i,n,sum,wt,tat,twt,ttat;
    int t[10];
    float awt,atat;
    clrscr();

    printf("Enter number of processors:\n");
    scanf("%d",&n);
    for(i=0;i<n;i++)
    {
        printf("\n Enter the Burst Time of the process %d",i+1);
        scanf("\n %d",&t[i]);
    }
    printf("\n\n FIRST COME FIRST SERVE SCHEDULING ALGORITHM \n");
    printf("\n Process ID \t Waiting Time \t Turn Around Time \n");
    printf("1 \t\t 0 \t\t %d \n",t[0]);
    sum=0;
    twt=0;
    ttat=t[0];
    for(i=1;i<n;i++)
    {
        sum+=t[i-1];
        wt=sum;
        tat=sum+t[i];
        twt=twt+wt;
        ttat=ttat+tat;
        printf("\n %d \t\t %d \t\t %d",i+1,wt,tat);
        printf("\n\n");
    }
}
```

```

}
awt=(float)twt/n;
atat=(float)ttat/n;
printf("\n Average Waiting Time %4.2f",awt);
printf("\n Average Turnaround Time %4.2f",atat);
getch();
}

```

## OUTPUT:

Enter number of processors:

3

Enter the Burst Time of the process 1: 2

Enter the Burst Time of the process 2: 5

Enter the Burst Time of the process 3: 4

## FIRST COME FIRST SERVE SCHEDULING ALGORITHM

Process ID	Waiting Time	Turn Around Time
1	0	2
2	2	7
3	7	11

Average Waiting Time 3.00

Average Turnaround Time 6.67

Ex. No: 1(d)

## PRIORITY SCHEDULING

Aim: Write a C program to implement the various process scheduling mechanisms such as Priority Scheduling.

### Algorithm for Priority Scheduling:

Step 1: Start the process

Step 2: Accept the number of processes in the ready Queue

Step 3: For each process in the ready Q, assign the process id and accept the CPU burst time

Step 4: Sort the ready queue according to the priority number.

Step 5: Set the waiting of the first process as '0' and its burst time as its turn around time

Step 6: For each process in the Ready Q calculate

(e) Waiting time for process(n)= waiting time of process (n-1) + Burst time of process(n-1)

(f) Turn around time for Process(n)= waiting time of Process(n)+ Burst time for process(n)

Step 7: Calculate

(g) Average waiting time = Total waiting Time / Number of process

(h) Average Turnaround time = Total Turnaround Time / Number of process

Step 8: Stop the process

```
/* PRIORITY SCHEDULING */
```

```
#include <stdio.h>
#include <conio.h>
void main()
{
    int i,j,n,tat[10],wt[10],bt[10],pid[10],pr[10],t,ttt=0,ttat=0;
    float awt,atat;
    clrscr();
    printf("\n-----PRIORITY SCHEDULING-----\n");
    printf("Enter the No of Process: ");
    scanf("%d", &n);
    for (i=0;i<n;i++)
    {
        pid[i] = i;
        printf("Enter the Burst time of Pid %d : ",i);
        scanf("%d",&bt[i]);
        printf("Enter the Priority of Pid %d : ",i);
        scanf ("%d",&pr[i]);
    }
    // Sorting start
    for (i=0;i<n;i++)
        for(j=i+1;j<n;j++)
        {
            if (pr[i] > pr[j] )
            {
                t = pr[i];
                pr[i] = pr[j];
                pr[j] = t;

                t = bt[i];
                bt[i] = bt[j];
                bt[j] = t;

                t = pid[i];
                pid[i] = pid[j];
                pid[j] = t;
            }
        }
}
```

```
// Sorting finished
```

```
tat[0] = bt[0];
wt[0] = 0;

for (i=1;i<n;i++)
{
    wt[i] = wt[i-1] + bt[i-1];
    tat[i] = wt[i] + bt[i];
}

printf("\n-----\n");
printf("Pid\t Priority\tBurst time\t WaitingTime\tTurnAroundTime\n");
printf("\n-----\n");
    for(i=0;i<n;i++)
    {
        printf("\n%d\t%d\t%d\t%d\t%d",pid[i],pr[i],bt[i],wt[i],tat[i]);

Avg.Turn Around Time: 10.750000

Exp no:2(a)            SEQUENTIAL FILE ALLOCATION

AIM: Write a C Program to implement Sequential File Allocation method.

## ALGORITHM:

- Step 1: Start the program.
- Step 2: Get the number of memory partition and their sizes.
- Step 3: Get the number of processes and values of block size for each process.
- Step 4: First fit algorithm searches all the entire memory block until a hole which is big enough is encountered. It allocates that memory block for the requesting process.
- Step 5: Best-fit algorithm searches the memory blocks for the smallest hole which can be allocated to requesting process and allocates it.
- Step 6: Worst fit algorithm searches the memory blocks for the largest hole and allocates it to the process.
- Step 7: Analyses all the three memory management techniques and display the best algorithm which utilizes the memory resources effectively and efficiently.
- Step 8: Stop the program.

## PROGRAM:

```
#include<stdio.h>
#include<conio.h>
main()
{
    int n,i,j,b[20],sb[20],t[20],x,c[20][20];
    clrscr();
    printf("Enter no.of files:");
    scanf("%d",&n);

## INDEXED FILE ALLOCATION

AIM: Write a C Program to implement Indexed File Allocation method.

Algorithm:

Step 1: Start.

Step 2: Let n be the size of the buffer

Step 3: check if there are any producer

Step 4: if yes check whether the buffer is full

Step 5: If no the producer item is stored in the buffer

Step 6: If the buffer is full the producer has to wait

Step 7: Check there is any cosumer.If yes check whether the buffer is empty

Step 8: If no the consumer consumes them from the buffer

Step 9: If the buffer is empty, the consumer has to wait.

Step 10: Repeat checking for the producer and consumer till required

Step 11: Terminate the process.

PROGRAM:

```
#include<stdio.h>
```

```
#include<conio.h>
```

```
main()
```

```

Enter no.of pages : 4  
Enter memory for OS :10

Enter size of page : 10  
Enter size of page : 9  
Enter size of page : 9  
Enter size of page : 10

External Fragmentation is = 2

AIM: Write a program to implement Dynamic allocation of memories in MVT.

Algorithm:

- Step1: start the process.
- Step2: Declare variables.
- Step3: Enter total memory size.
- Step4: Allocate memory for os.
- Step5: allocate total memory to the pages.
- Step6: Display the wastage of memory.
- Step7: Stop the process.

PROGRAM:

```
#include<stdio.h>
#include<conio.h>
main()
{
```

```

int ms,i,ps[20],n,size,p[20],s,intr=0;
clrscr();
printf("Enter size of memory:");
scanf("%d",&ms);
printf("Enter memory for OS:");
scanf("%d",&s);
ms-=s;
printf("Enter no.of partitions to be divided:");
scanf("%d",&n);
size=ms/n;
for(i=0;i<n;i++)
{
    printf("Enter process and process size");
    scanf("%d%d",&p[i],&ps[i]);
    if(ps[i]<=size)
    {
        intr=intr+size-ps[i];
        printf("process%d is allocated\n",p[i]);
    }
    else
        printf("process%d is blocked",p[i]);
}
printf("total fragmentation is %d",intr);
getch();
}

```

OUTPUT:

Enter total memory size : 50

Enter memory for OS :10

Enter no.of partitions to be divided:4

Enter size of page : 10

Enter size of page : 9

Enter size of page : 9

Enter size of page : 8

Internal Fragmentation is = 4

## Ex. No: 4          BANKER'S ALGORITHM

AIM: To implement deadlock avoidance & Prevention by using Banker's Algorithm.

Deadlock avoidance & Dead Lock Prevention

Banker's Algorithm:

When a new process enters a system, it must declare the maximum number of instances of each resource type it needed. This number may exceed the total number of resources in the system. When the user request a set of resources, the system must

determine whether the allocation of each resources will leave the system in safe state. If it will the resources are allocation; otherwise the process must wait until some other process release the resources.

#### Data structures

- n-Number of process, m-number of resource types.
- Available: Available[j]=k, k – instance of resource type R<sub>j</sub> is available.
- Max: If max[i, j]=k, P<sub>i</sub> may request at most k instances resource R<sub>j</sub>.
- Allocation: If Allocation [i, j]=k, P<sub>i</sub> allocated to k instances of resource R<sub>j</sub>
- Need: If Need[I, j]=k, P<sub>i</sub> may need k more instances of resource type R<sub>j</sub>,  
Need[I, j]=Max[I, j]-Allocation[I, j];

#### Safety Algorithm

1. Work and Finish be the vector of length m and n respectively,  
Work=Available and Finish[i] =False.
2. Find an i such that both
  - Finish[i] =False
  - Need<=WorkIf no such I exists go to step 4.
3. work=work+Allocation, Finish[i] =True;
4. if Finish[1]=True for all I, then the system is in safe state.

#### Resource request algorithm

Let Request i be request vector for the process P<sub>i</sub>, If request i=[j]=k, then process P<sub>i</sub> wants k instances of resource type R<sub>j</sub>.

1. if Request<=Need I go to step 2. Otherwise raise an error condition.
2. if Request<=Available go to step 3. Otherwise P<sub>i</sub> must since the resources are available.
3. Have the system pretend to have allocated the requested resources to process P<sub>i</sub> by modifying the state as follows;  
Available=Available-Request I;  
Allocation I =Allocation+Request I;  
Need i=Need i-Request I;

If the resulting resource allocation state is safe, the transaction is completed and process P<sub>i</sub> is allocated its resources. However if the state is unsafe, the P<sub>i</sub> must wait for Request i and the old resource-allocation state is restored.

#### ALGORITHM:

1. Start the program.
2. Get the values of resources and processes.
3. Get the avail value.
4. After allocation find the need value.
5. Check whether its possible to allocate.
6. If it is possible then the system is in safe state.
7. Else system is not in safety state.

8. If the new request comes then check that the system is in safety.
9. or not if we allow the request.
10. stop the program.

```
/* BANKER'S ALGORITHM */  
  
#include<stdio.h>  
#include<conio.h>  
struct da  
{  
    int max[10],a1[10],need[10],before[10],after[10];

## PAGING

Aim: To implement the Memory management policy- Paging.

Algorithm:

Step 1: Read all the necessary input from the keyboard.

Step 2: Pages - Logical memory is broken into fixed - sized blocks.

Step 3: Frames – Physical memory is broken into fixed – sized blocks.

Step 4: Calculate the physical address using the following

$$\text{Physical address} = (\text{Frame number} * \text{Frame size}) + \text{offset}$$

Step 5: Display the physical address.

Step 6: Stop the process.

```

/* Memory Allocation with Paging Technique */

#include <stdio.h>

### OUTPUT:

#### MEMORY MANAGEMENT USING PAGING

Enter the Size of Physical memory: 16

Enter the size of Logical memory: 8

Enter the partition size: 2

The physical memory is divided into 8 no.of frames

The Logical memory is divided into 4 no.of pages

Enter the Frame number where page 0 must be placed: 5

Enter the Frame number where page 1 must be placed: 6

Enter the Frame number where page 2 must be placed: 7

Enter the Frame number where page 3 must be placed: 2

#### PAGE TABLE

PageAddress	FrameNo.	PresenceBit
0	5	1
1	6	1
2	7	1
3	2	1

#### FRAME TABLE

FrameAddress	PageNo
0	32555
1	32555
2	3
3	32555
4	32555
5	0
6	1
7	2

Process to create the Physical Address

Enter the Base Address: 1000

Enter the Logical Address: 3

The Physical Address where the instruction present: 1013  
Ex. No:7                                      SEGMENTATION

AIM:

To implement the memory management policy-segmentation.

ALGORITHM:

- Step 1: Start the program.
- Step 2: Get the number of segments.
- Step 3: get the base address and length for each segment.
- Step 4: Get the logical address.
- Step 5: check whether the segment number is within the limit, if not display the error message.
- Step 6: Check whether the byte reference is within the limit, if not display the error message.
- Step 7: Calculate the physical memory and display it.
- Step 8: Stop the program.
